

Adaptive Boosting 報告

資工四 408410086 常博愛

1.

```
8 %%
9 function boosted=adaBoost(train,train_label,cycles)
10     disp('running adaBoost algorithm');
11     d=size(train);
12     distribution=ones(1,d(1))/d(1);
13     error=zeros(1,cycles);
14     beta=zeros(1,cycles);
15     label=(train_label(:)>=5);% contain the correct label per vector
16     for j=1:cycles
17         if(mod(j,10)==0)
18             disp([j,cycles]);
19         end
20         [i,t]=weakLearner(distribution,train,label);
21         error(j)=distribution*abs(label-(train(:,i)>=t));
22         beta(j)=error(j)/(1-error(j));
23         boosted(j,:)=beta(j),i,t;
24         distribution=distribution.* exp(log(beta(j))*(1-abs(label-(train(:,i)>=t))))';
25         distribution=distribution/sum(distribution);
26     end
27
```

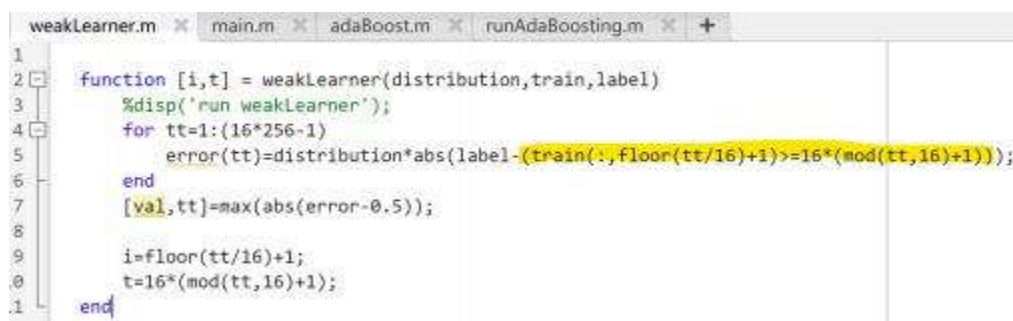

Parameters:

1. train : training data
2. train_label : 每筆 training data 的答案
3. cycle : 要做多少 iterations (課程投影片的 T)

2.

資料的形式應該是一個 row 就是一筆資料，每個 column 就是他的各個 feature 。

How to decide :

```
1
2 function [i,t] = weakLearner(distribution,train,label)
3     %disp('run weakLearner');
4     for tt=1:(16*256-1)
5         error(tt)=distribution*abs(label-(train(:,floor(tt/16)+1)>=16*(mod(tt,16)+1))));
6     end
7     [val,tt]=max(abs(error-0.5));
8
9     i=floor(tt/16)+1;
10    t=16*(mod(tt,16)+1);
11 end
```

使用16個 $h_k(x) = s \cdot (x_j - \theta)$, where $\theta_k = 16 * 1, 16 * 2, 16 * 3, \dots, 16 * 16$; $s = 1$ 。

在 $256 \times 16 - 1 = 4095$ 個產生的 predictions 中，每 16 個一組，共 256 組，每組代表一個 feature，會依據該 feature 產生 16 個 predictions

但是他這樣寫 `for i=1:(16*256)-1`，那第一個 feature 好像只會產生 15 個 predictions？

predictions for a single data $\text{train}[j] =$

$$\begin{bmatrix} h_1(x_{j,1}) & h_2(x_{j,1}) & \dots & h_{16}(x_{j,1}) \\ h_1(x_{j,2}) & h_2(x_{j,2}) & \dots & h_{16}(x_{j,2}) \\ \vdots & \vdots & \ddots & \vdots \\ h_1(x_{j,256}) & h_2(x_{j,256}) & \dots & h_{16}(x_{j,256}) \end{bmatrix}$$

($j = 1 \rightarrow 15$ for $\text{floor}(i/16)+1 = 1, \theta = 16 * 2, \dots 16 * 16$)

Learning Algorithm A (i.e How to train the weaklearner ?)

```
weakLearner.m x main.m x adaBoost.m x runAdaBoosting.m x +
function [i,t] = weakLearner(distribution,train,label)
%disp('run weakLearner');
for tt=1:(16*256-1)
    error(tt)=distribution*abs(label-(train(:,floor(tt/16)+1)>=16*(mod(tt,16)+1)));
end
[val,tt]=max(abs(error-0.5));
i=floor(tt/16)+1;
t=16*(mod(tt,16)+1);
end
```

$16 \times 256 - 1 = 4095$ 個 errors，16 個一組 (第一組只有 15 個)，為每個 feature i 使用不同的 h_k (16 個) 的 predictions 與 groundtruth 的異 (1) 同 (0) $\times \text{distribution}_i^t$ 相加 (他使用 dot 的做法加速)

(distribution 為上課程投影片的 u)。

0.5 的錯誤率代表隨機，所以與 0.5 差距最大就代表使用 $h_k(x_i)$ 最為精準 (不管是正面的還是負面的最準)。

所以，就去找哪一個被 tt index 到的 $\theta_t = 16 * (tt \% 16 + 1)$ 以及其對應的 feature index i 所產生出來的 error 與 0.5 差距最大的，傳回去，為更新 distribution (u) 做準備。

Does it use bootstrapped dataset? & How D^t is obtain for each iteration?

```
for j=1:cycles
    %if(mod(j,10)==0)
    %    disp([j,cycles]);
    %end
    [i,t]=weakLearner(distribution,train,label);
    error(j)=distribution*abs(label-(train(:,i)>=t));
    beta(j)=error(j)/(1-error(j));
    boosted(j,:)= [beta(j),i,t];
    distribution=distribution.* exp(log(beta(j))*(1-abs(label-(train(:,i)>=t))))';
    distribution=distribution/sum(distribution);
end
```

他沒有使用 bootstrapped dataset。每一次的 iteration 他是直接把傳進來的 train 全部傳入 weakLearner 裡面。

3.

其中綠色的部分可以看到，他並沒有把 $x_i - \theta_i$ 的結果再去乘以其他數字，所以應該 s 都 $= 1$

$h = [\text{train}(:, i) \geq t]$

$\Rightarrow h = 1 * \text{sign}(\text{train}(:, i) - t)$

```
function boosted=adaBoost(train,train_label,cycles)
    disp('running adaBoost algorithm');
    d=size(train);
    distribution=ones(1,d(1))/d(1); %u
    error=zeros(1,cycles);
    beta=zeros(1,cycles);
    label=(train_label(:)>=5);% contain the correct label per vector
    for j=1:cycles
        %if(mod(j,10)==0)
        %    disp([j,cycles]);
        %end
        [i,t]=weakLearner(distribution,train,label);
        error(j)=distribution*abs(label-(train(:,i)>=t));
        beta(j)=error(j)/(1-error(j));
        boosted(j,:)=[beta(j),i,t];

        distribution=distribution.* exp(log(beta(j))*(1-abs(label-(train(:,i)>=t))))';
        distribution=distribution/sum(distribution); %normalize to 0~1
        if j < 4
            fprintf('%d turns\n, featureID=%d, theta=%d\n',j,i,t);
            fprintf('blending weight = %f\n',log(beta(jX)));
        end
    end
end
```

他的實驗有兩部分:

- 在相同 iterations(100)下，training 使用 100, 200, ... 1000 (whole data)
- iterations 不同: 20, 40, ... ,100

其中，若使用 data 數量一樣，則前3個iterations 情況都相同。

#data	3 iterations (i, θ)
100	(170,160), (26,192), (74,144)
200	(170,128), (10,64), (29,192)
300	(11,16), (170,128), (26,160)
400	(11,16), (170,128), (74,16)
500	(11,16), (170,128), (74,16)
600	(11,16), (170,80), (74,16)
700	(11,16), (170,80), (74,16)
800	(11,80), (170,80), (74,16)
900	(11,80), (170,80), (58,16)

#data	3 iterations (j, θ)
1000(whole)	(11,80), (170,80), (58,16)

4.

blending weight:

```

1 %%
2 % file: getError.m
3 % This function calculates the error returned by the current run of the weak learner.
4 %%
5 function [errorTrain,errorTest]=getError(boost,train,train_label,test,test_label)
6     disp('run getError');
7     d=size(boost);
8     num=size(train);
9     prediction=zeros(num(1),1);
10    % getting the train error
11    for h=1:d(1)
12        prediction=prediction-log(boost(h,1))*(train(:,boost(h,2))>=boost(h,3));
13    end
14    temp=-sum(log(boost(:,1)))/2;
15    errorTrain=sum(abs((train_label>=5)-(prediction>=temp)))/num(1);
16    prediction=zeros(1000,1);
17    % getting the test error
18    for h=1:d(1)
19        prediction=prediction-log(boost(h,1))*(test(:,boost(h,2))>=boost(h,3));
20    end
21    errorTest=sum(abs((test_label>=5)-(prediction>=temp)))/1000;
22

```

可以看到 blending weight 在程式中是使用 $\log(\text{boost}(h,1))$ 而回追回去 boost:

```

8 %%
9 function boosted=adaBoost(train,train_label,cycles)
10     disp('running adaBoost algorithm');
11     d=size(train);
12     distribution=ones(1,d(1))/d(1); %u
13     error=zeros(1,cycles);
14     beta=zeros(1,cycles);
15     label=(train_label(:)>=5);% contain the correct label per vector
16     for j=1:cycles
17         %if(mod(j,10)==0)
18             % disp([j,cycles]);
19         %end
20         [i,t]=weakLearner(distribution,train,label);
21         error(j)=distribution*abs(label-(train(:,i)>=t));
22         beta(j)=error(j)/(1-error(j));
23         boosted(j,:)=beta(j),i,t;
24
25         distribution=distribution.* exp(log(beta(j))*(1-abs(label-(train(:,i)>=t))))';
26         distribution=distribution/sum(distribution); %normalize to 0~1
27         if j < 4
28             fprintf('%d turns\n, featureID=%d, theta=%d\n',j,i,t);
29             fprintf('blending weight = %f\n',log(beta(j)));
30         end
31     end
32 end
33

```

boosted(j, 1) 就是 $\sqrt{\frac{\epsilon_t}{1-\epsilon_t}}$ 所以 blending weight = $\ln(\sqrt{\frac{\epsilon_t}{1-\epsilon_t}})$

#data	3 iterations blending weight
100	- 1.098612, - 1.227230, 1.007370

#data	3 iterations blending weight
